## Key Question

How do we implement a general, automated spacecraft planning framework with hard safety specifications?

Future Goals

## Our work:

1. Establishes a **provably-correct framework** for the *systematic* encoding of safety specifications into the spacecraft trajectory generation process
2. Derives an efficient **one-burn escape maneuver policy** for proximity operations near circular orbit

ISS026E030181

CWH CAM Policy Design

Numerical  
Experiments

Conclusions

Future Goals

Spacecraft rendezvous approaches with explicit characterizations of safety:

- Kinematic path optimization [*Jacobsen, Lee, et al., 2002*]
- Artificial potential functions [*Roger and McInnes, 2000*]
- MILP formulations [*Breger and How, 2008*]
- Safety ellipses [*Gaylor and Barbee, 2007*] [*Naasz, 2005*]
- Motion planning [*Frazzoli, 2003*]
- Robust Model-Predictive Control [*Carson, Aćikmeşe, et al., 2008*]
- Forced equilibria [*Weiss, Baldwin, et al., 2013*]

Constraints

CWH CAM Policy Design

Numerical  
Experiments

Conclusions  
Future Goals

- **Passive Trajectory Protection:** Constrain coasting trajectories to avoid collisions up to a given horizon time
- **Active Trajectory Protection:** Implement an *actuated escape maneuver* to save/abort a mission

## Design Choice

We emphasize *active safety* as it is the less-conservative approach

## Definition (Trajectory Safety Problem)

For all possible failure times  $t_{\text{fail}} \in \mathcal{T}_{\text{fail}}$  and failure modes  $\mathcal{U}_{\text{fail}}(\mathbf{x}(t_{\text{fail}}))$ , we seek a sequence of admissible actions  $\mathbf{u}(\tau) \in \mathcal{U}_{\text{fail}}(\mathbf{x}(t_{\text{fail}}))$  from  $\mathbf{x}(t_{\text{fail}})$  such that the remaining trajectory is safe.

### Examples:

- **Rovers/Land vehicles:** Come to a complete stop
- **Manipulators:** Return to previous configuration, disengage, or execute emergency plan
- **UAV's:** Enter a safe loiter pattern
- **Spacecraft:** Less straightforward; generally require mission-specific solutions (with human oversight)

# Idea: Positively-Invariant Sets

## Definition (Positively-Invariant Set)

A set  $\mathcal{X}_{\text{invariant}}$  is positively invariant with respect to  $\dot{\mathbf{x}} = f(\mathbf{x})$  if and only if

$$\mathbf{x}(t_0) \in \mathcal{X}_{\text{invariant}} \implies \mathbf{x}(t) \in \mathcal{X}_{\text{invariant}}, t \geq t_0$$

$$\begin{aligned} & \underset{t_f, \mathbf{x}(t), \mathbf{u}(t)}{\text{minimize}} \quad J(\mathbf{x}, \mathbf{u}, t) \\ \text{subject to} \quad & \dot{\mathbf{x}}(t) = f(\mathbf{x}(t), \mathbf{u}(t), t) \quad (\text{Dynamics}) \\ & \mathbf{x}(t_0) = \mathbf{x}_0 \quad (\text{Initial Condition}) \\ & \mathbf{x}(t_f) \in \mathcal{X}_{\text{invariant}} \quad (\text{Invariant Termination}) \\ & \mathbf{u}(t) \in \mathcal{U}_{\text{fail}}(\mathbf{x}_0) \quad (\text{Control Admissibility}) \\ & g_i(\mathbf{x}, \mathbf{u}) \leq 0, i = [1, \dots, p] \quad (\text{Inequality Constraints}) \\ & h_j(\mathbf{x}, \mathbf{u}) = 0, j = [1, \dots, q] \quad (\text{Equality Constraints}) \end{aligned}$$

# Challenge: Solving the Finite-Time Safety Problem under Failures

For a  $K$ -fault tolerant spacecraft with  $N$  control components (thrusters, momentum wheels, CMG's, etc), this yields:

$$N_{\text{fail}} = \sum_{k=0}^K \binom{N}{k} = \sum_{k=0}^K \frac{N!}{k!(N-k)!}$$

total optimization problems (one for each  $\mathcal{U}_{\text{fail}}$ ) for each failure time  $t_{\text{fail}}$ .

Conclusions

Future Goals

## Theorem (Sufficient Fault-Tolerant Active Safety)

1. From each  $\mathbf{x}(t_{fail})$ , prescribe a Collision-Avoidance Maneuver  $\Pi_{CAM}(\mathbf{x})$  that gives a horizon  $T$  and escape sequence  $\mathbf{u}$  that satisfies  $\mathbf{x}(T) \in \mathcal{X}_{invariant}$  and  $\mathbf{u}(\tau) \subset \mathcal{U}$  for all  $t_{fail} \leq \tau \leq T$ .
2. For each failure mode  $\mathcal{U}_{fail}(\mathbf{x}(t_{fail})) \subset \mathcal{U}(\mathbf{x}(t_{fail}))$  up to tolerance  $K$ , check if  $\mathbf{u} = \Pi_{CAM}(\mathbf{x}) \subset \mathcal{U}_{fail}$ .

## Theorem (Sufficient Fault-Tolerant Active Safety)

1. From each  $\mathbf{x}(t_{fail})$ , prescribe a Collision-Avoidance Maneuver  $\Pi_{CAM}(\mathbf{x})$  that gives a horizon  $T$  and escape sequence  $\mathbf{u}$  that satisfies  $\mathbf{x}(T) \in \mathcal{X}_{invariant}$  and  $\mathbf{u}(\tau) \subset \mathcal{U}$  for all  $t_{fail} \leq \tau \leq T$ .
2. For each failure mode  $\mathcal{U}_{fail}(\mathbf{x}(t_{fail})) \subset \mathcal{U}(\mathbf{x}(t_{fail}))$  up to tolerance  $K$ , check if  $\mathbf{u} = \Pi_{CAM}(\mathbf{x}) \subset \mathcal{U}_{fail}$ .

## Key Simplifications

Removes decision variables  $\mathbf{u}$ , reducing to:

- a test of escape control feasibility under failure(s)
- numerical integration for satisfaction of dynamics
- an *a posteriori* check of constraints  $g_i$  and  $h_j$

Sampling-Based

Constraints

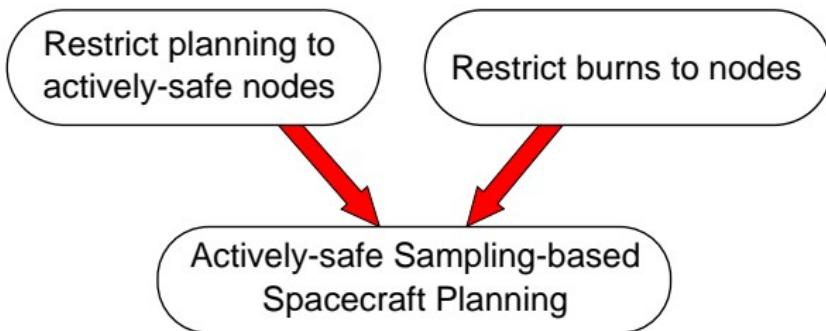

CWH CAM Policy Design

Numerical  
Experiments

Conclusions

Future Goals

- Simulates an automated approach to LandSat-7 (e.g., for servicing) between pre-specified waypoints
- Calls on the Fast Marching Tree (FMT\*) algorithm for implementation

## Assumptions:

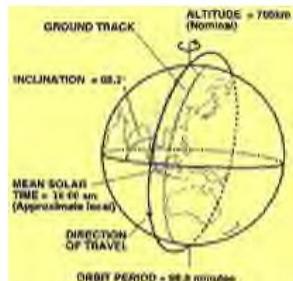

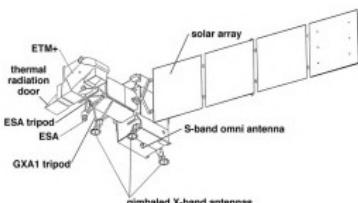

- Begins at insertion into a coplanar circular orbit sufficiently close to the target
- The target is nadir-pointing
- The chaser is nominally nadir-pointing, or executes a “turn-burn-turn” along CAMs

- Simulates an automated approach to LandSat-7 (e.g., for servicing) between pre-specified waypoints
- Calls on the Fast Marching Tree (FMT\*) algorithm for implementation

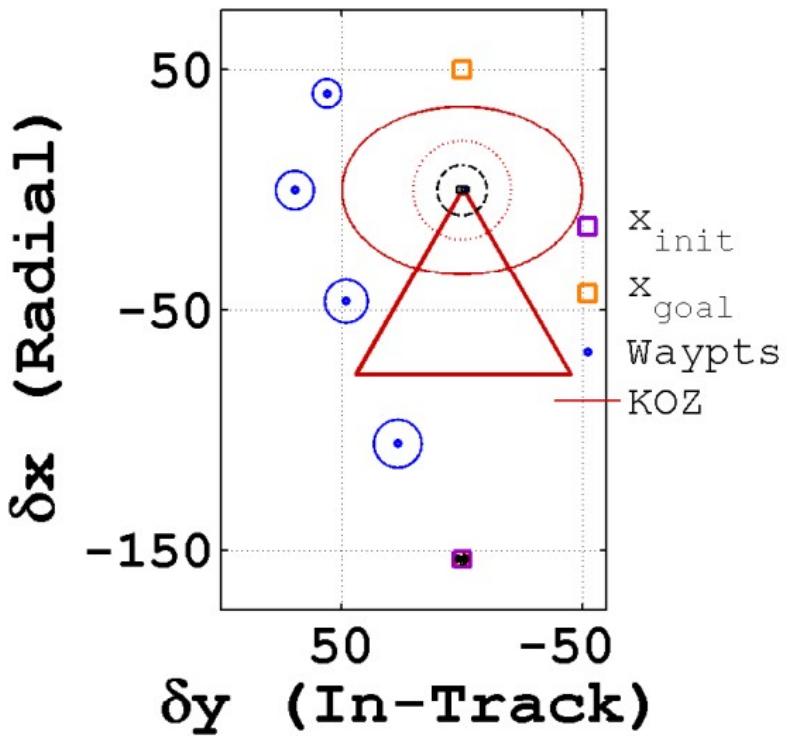

## Constraints:

- **Plume impingement:** No exhaust plume impingement
- **Collision avoidance:** Clearance of an elliptic Keep-Out Zone (KOZ)
- **Target communication:** Target comm lobe avoidance
- **Safety:** Two-fault tolerance to stuck-off failures

# Clohessy-Wiltshire-Hill (CWH) Equations

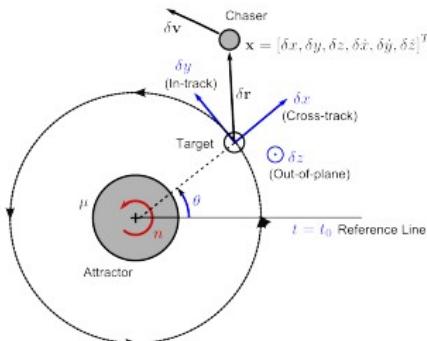

- Motion is linearized about a moving reference point in circular orbit:

$$\mathbf{x} = [\delta x, \delta y, \delta z, \delta \dot{x}, \delta \dot{y}, \delta \dot{z}]^T$$

$$\mathbf{u} = \frac{1}{m} [F_x, F_y, F_z]^T$$

- Yields LTI dynamics:  
 $\dot{\mathbf{x}} = \mathbf{Ax} + \mathbf{Bu}$

$$\mathbf{A} = \begin{bmatrix} 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 3n_{\text{ref}}^2 & 0 & 0 & 0 & 2n_{\text{ref}} & 0 \\ 0 & 0 & 0 & -2n_{\text{ref}} & 0 & 0 \\ 0 & 0 & -n_{\text{ref}}^2 & 0 & 0 & 0 \end{bmatrix} \quad \mathbf{B} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Barbee, M. Pavone

Dynamics

Sampling-Based  
Motion Planning

Optimal Motion Planning  
FMT\*

## Definition (Optimal Motion Planning Problem)

Given  $\mathcal{X}$ ,  $\mathcal{X}_{\text{obs}}$ ,  $\mathcal{X}_{\text{free}}$ , and  $J$ , find an action trajectory  $\mathbf{u} : [0, T] \rightarrow \mathcal{U}$  yielding a feasible path  $\mathbf{x}(t) \in \mathcal{X}_{\text{free}}$  over *time horizon*  $t \in [0, T]$ , which reaches the *goal region*  $\mathbf{x}(T) \in \mathcal{X}_{\text{goal}}$  and *minimizes* the cost functional  $J = \int_0^T c(\mathbf{x}(t), \mathbf{u}(t)) dt$ .

## Characteristics:

- PSPACE-hard (and therefore NP-hard)
- Requires kinodynamic motion planning
- Almost certainly requires approximate algorithms, tailored to the particular application
